

First Results from the Layered Atlantic Smoke Interactions with Clouds' (LASIC) AMF1 Deployment in the Remote Southeast Atlantic

Paquita Zuidema, Rodrigo Delgadillo, Lakshmi Chandra Jianhao Zhang, Yemi Adebiyi U of Miami, pzuidema@miami.edu

Motivation

Southern Africa emits one-third of the world's biomass burning aerosols (BBA), seasonally transported westward over the least examined of the large planetary subtropical stratocumulus decks. Satellite datasets cannot characterize the aerosol-cloud vertical structure with confidence. The aerosol direct radiative effect is still poorly known, as are the processes by which the clouds adjust to the presence

of the smoke. Most surface-based insitu and remote sensing LASIC aerosol and cloud measurements on Ascension Island (8S, 14W, halfway between Africa and south America) began June 1, 2016, providing an unprecedented characterization of a BBA aerosol seasons. Instrument health has been good. **Guiding questions** include:

• Does BBA reach the surface? This is not only crucial for surface-based aerosol characterization, but also for understanding the low cloud response. • If so, how does the single-scattering albedo (SSA) of the BBA evolve over the BBA season?

This is important for the direct radiative effect and for the atmospheric radiative heating rate profiles. • How do the low cloud properties change when BBA is present, either in the free troposphere or within the boundary layer or both?

Surface cloud observations provide clues two-layer low cloud structure more prevalent in BBA months when inversion is stronger (IGRA radiosondes not shown)

Alison Aiken, Connor Flynn, Art Sedlacek, The LASIC Working Group, aircraft deployment collaborators Jens Redemann, Robert Wood, Jim Haywood, ARM Logistics Kim Nitschke, Amon Haruta, Heath Powers, the Radar Working Group, instrument mentors and many more

between July 1 -35 30 Oct 30, 2016, in at times 20 significant '특 amounts $(>1.5 \ \mu g/m^3)$. High loadings are remarkable given Ascension is ~1700 km offshore of Africa.

How do the low clouds respond to the presence of BBA? WE DON'T YET KNOW

Does biomass-burning aerosol reach the surface? YES some absorbing aerosol almost always reached the surface July-October 2016 Ascension Island corrected aerosol absorption coefficients (PSAP) Virkkula-Bonc | differences | Single Particle Soot Photometer (SP2) derived black carbon mass concentrations (Art Sedlacek)

0.90 0.85 0.80 VSS 0.75 0.70 0.65 0.60

Estimated SSA values span 0.70-0.75 at high aerosol loadings differing by > 0.5 depending on correction scheme. The absorbing angstrom exponent is ~ 1.3 for much of July-Oct (not shown). These values indicate more absorption and a higher black carbon fraction than documented for US wildfires (Liu, Aiken et al., 2014,GRL). Why??

NASA EVS-2 ORACLES 2016, 2017 P-3 & ER-2 aircraft PI J. Redemann, Deputy PI R. Wood deploys from Namibia. UK CLARIFY 2017 FAAM BAe-146 aircraft. PI J. Haywood, will deploy from Ascension Aug-Sept 2017

How much sunlight does the BBA absorb? A LOT
