# Probing rBC Mixing State

Wildfires offer a **unique** set of **conditions** that favor a variety of rBC-containing particle morphologies.

- rBC – POA coagulation
- condensation of organic material on rBC

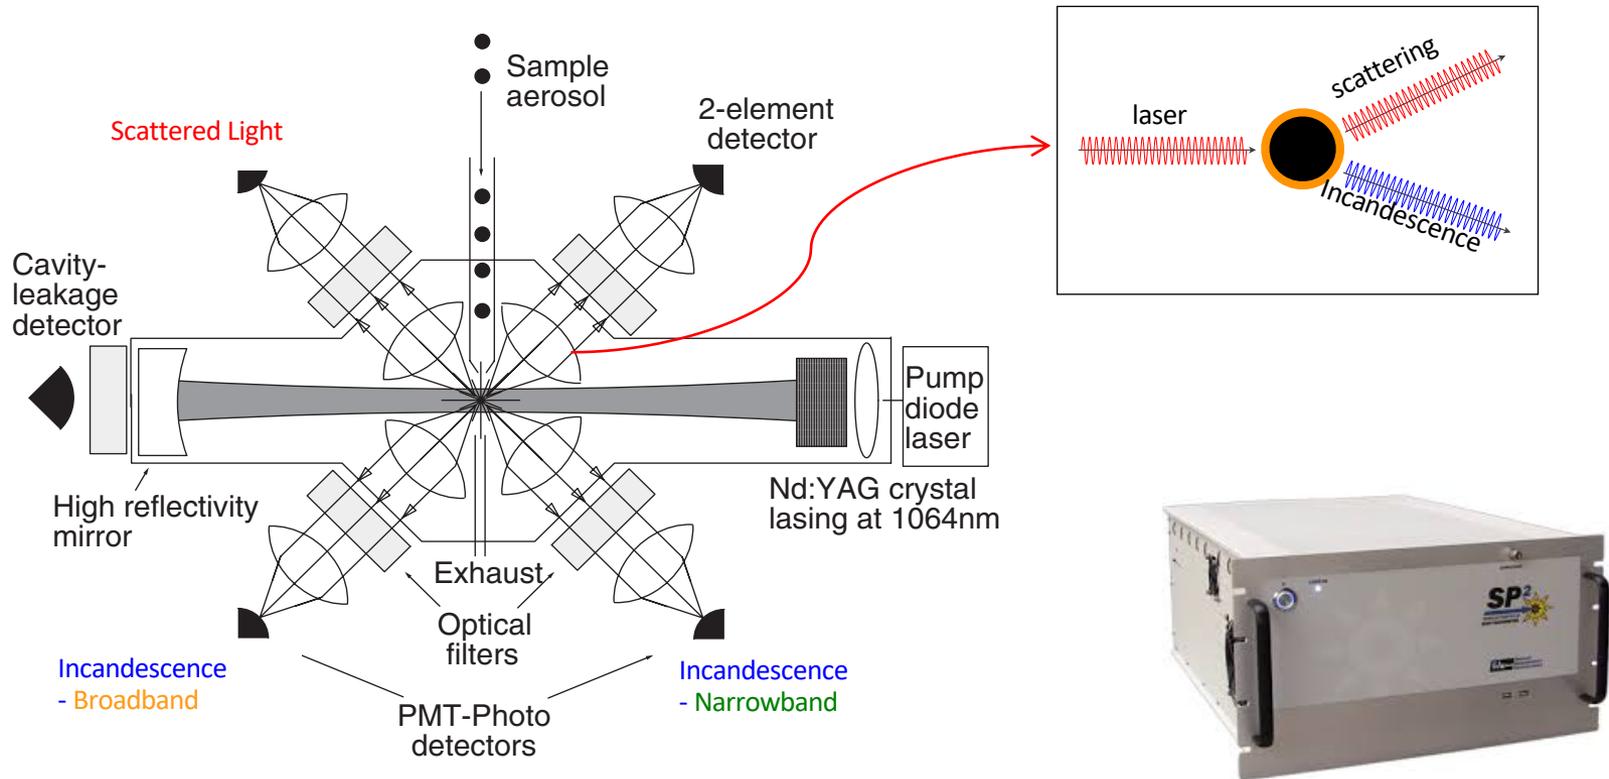

Today's discussion: Assume an idealized "core-shell" morphology

Next we probe the *potential* microphysical and optical implications of the derived rBC mixing state.

# Probing Refractory Black Carbon (rBC) Mixing State

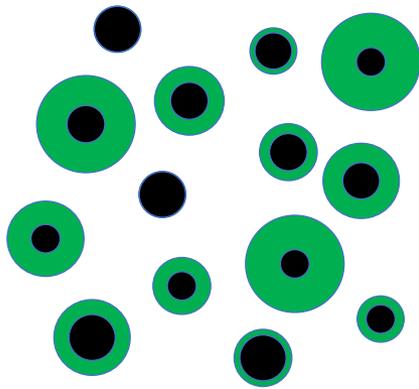

Detection of refractory black carbon (rBC) using laser-induced incandescence

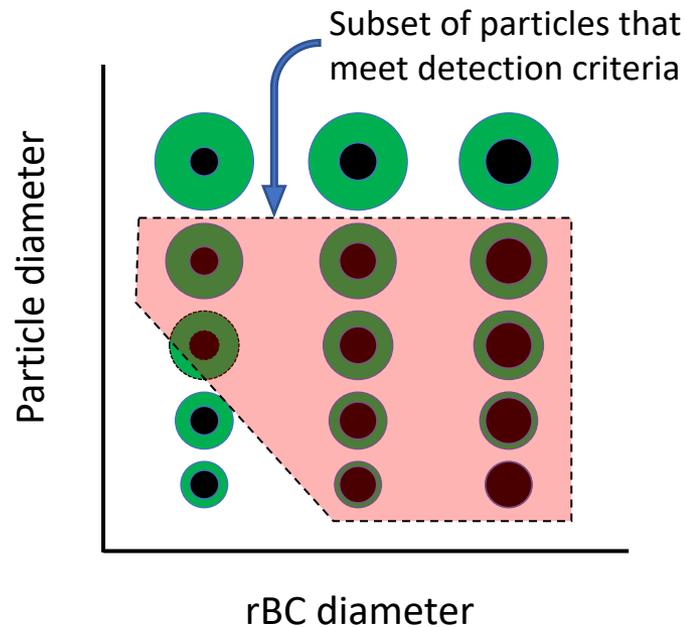

Schematic from Schwarz et al., 2008

# Refractory Black Carbon (rBC) Mixing State

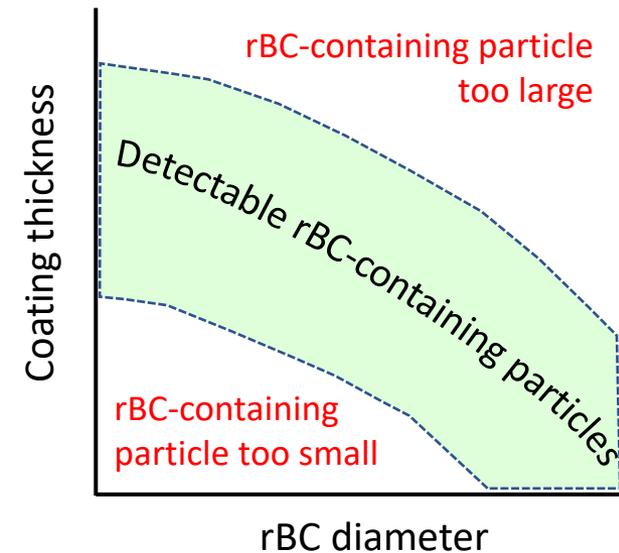

Use scattering and incandescence signals from individual rBC containing particles to probe rBC mixing state (i.e., coating thickness distribution as a function of rBC core diameter)

Distribution of rBC-containing particles

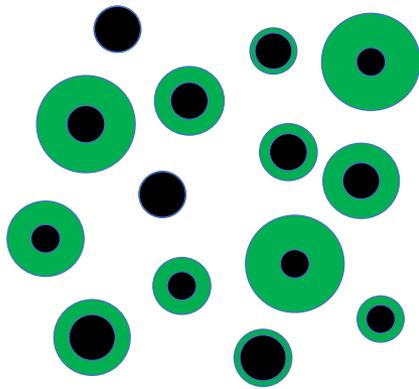

Classification of "total" particle diameter and core diameter using valid scattering & incandescence signals

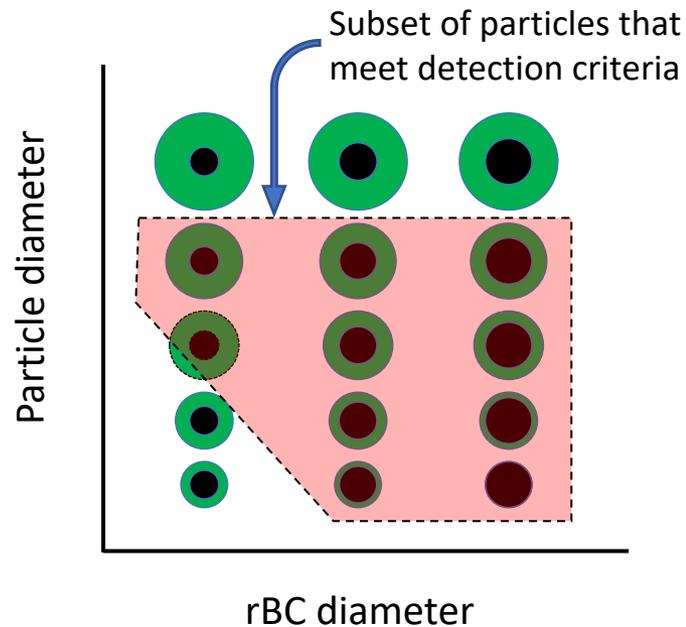

Plot a distribution of coating thicknesses for a given rBC core diameter

# Refractory Black Carbon (rBC) Mixing State

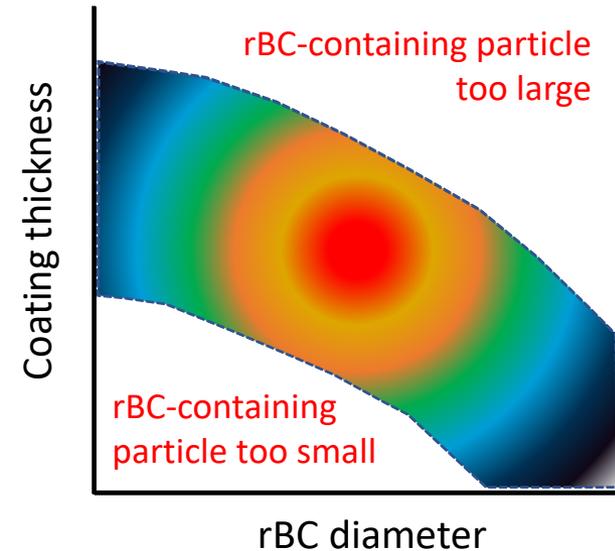

Use scattering and incandescence signals from individual rBC containing particles to probe rBC mixing state (i.e., coating thickness distribution as a function of rBC core diameter)

Distribution of rBC-containing particles

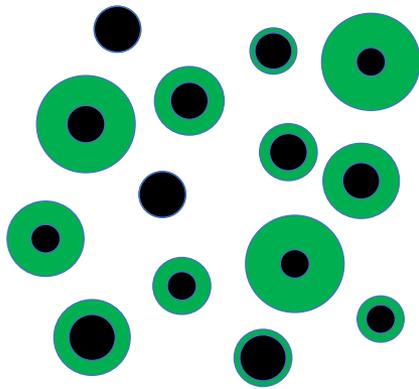

Classification of "total" particle diameter and core diameter using valid scattering & incandescence signals

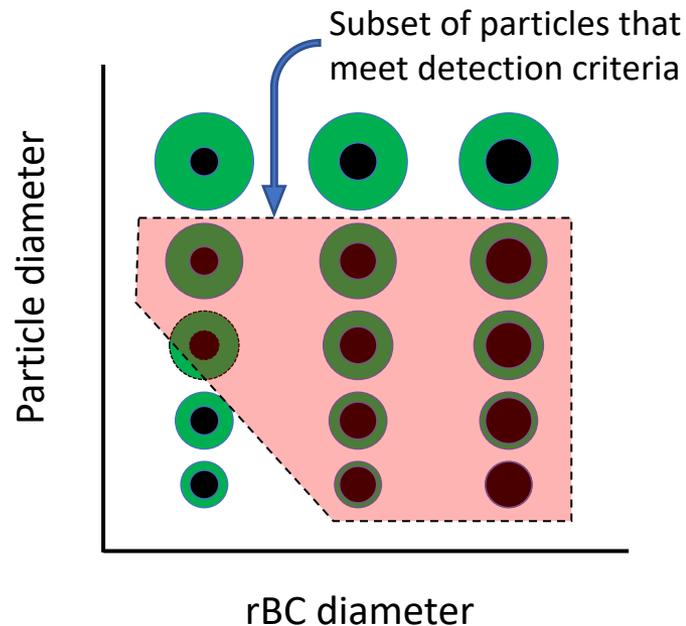

Plot a distribution of coating thicknesses for a given rBC core diameter

# Refractory Black Carbon (rBC) Mixing State

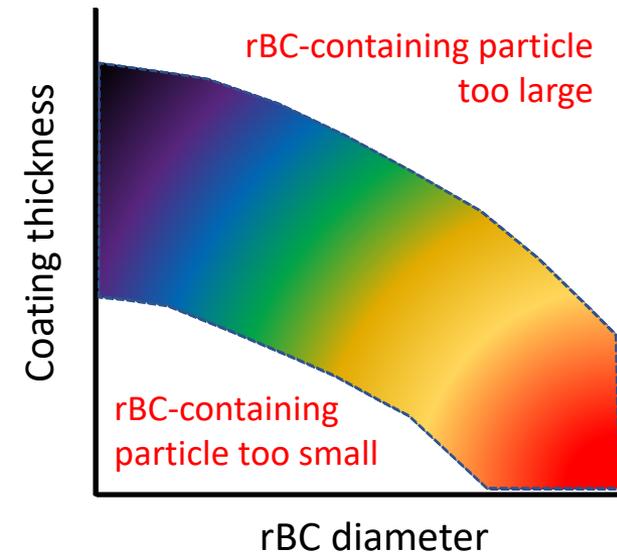

Use scattering and incandescence signals from individual rBC containing particles to probe rBC mixing state (i.e., coating thickness distribution as a function of rBC core diameter)

Distribution of rBC-containing particles

# rBC Particle Mixing States from LASIC & ORACLES

SSA ~ 0.9

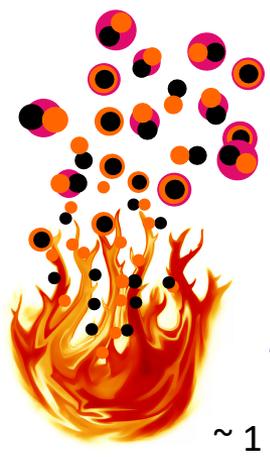

ISO inlet

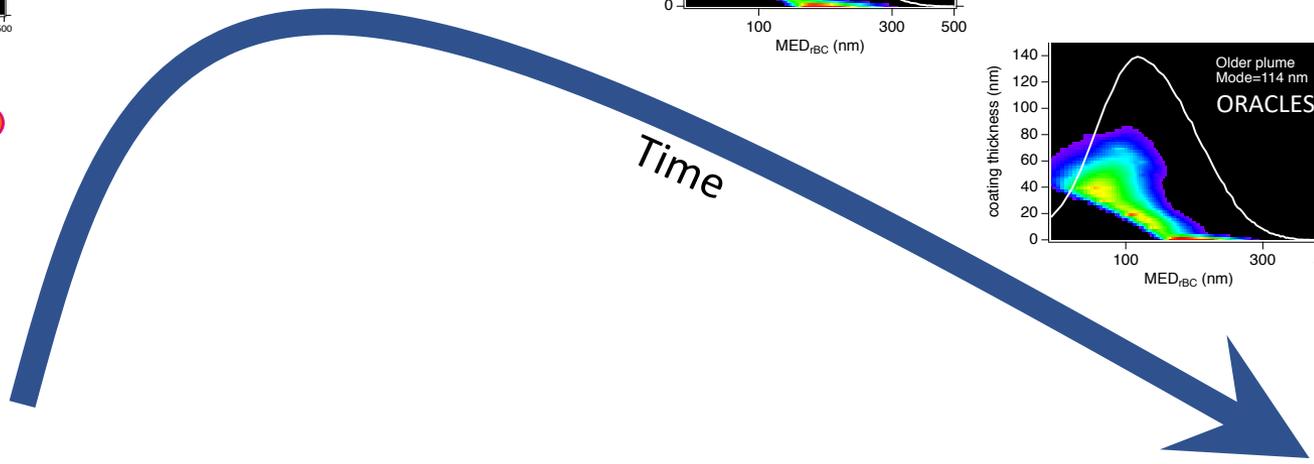

In cloud (CVI inlet)

SSA ~ 0.8

~ 1 day

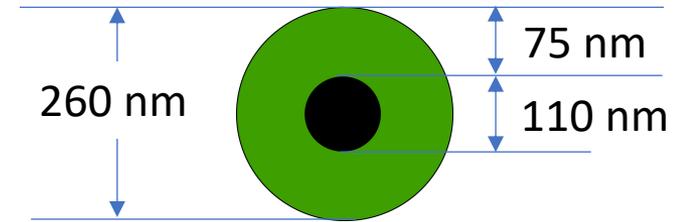

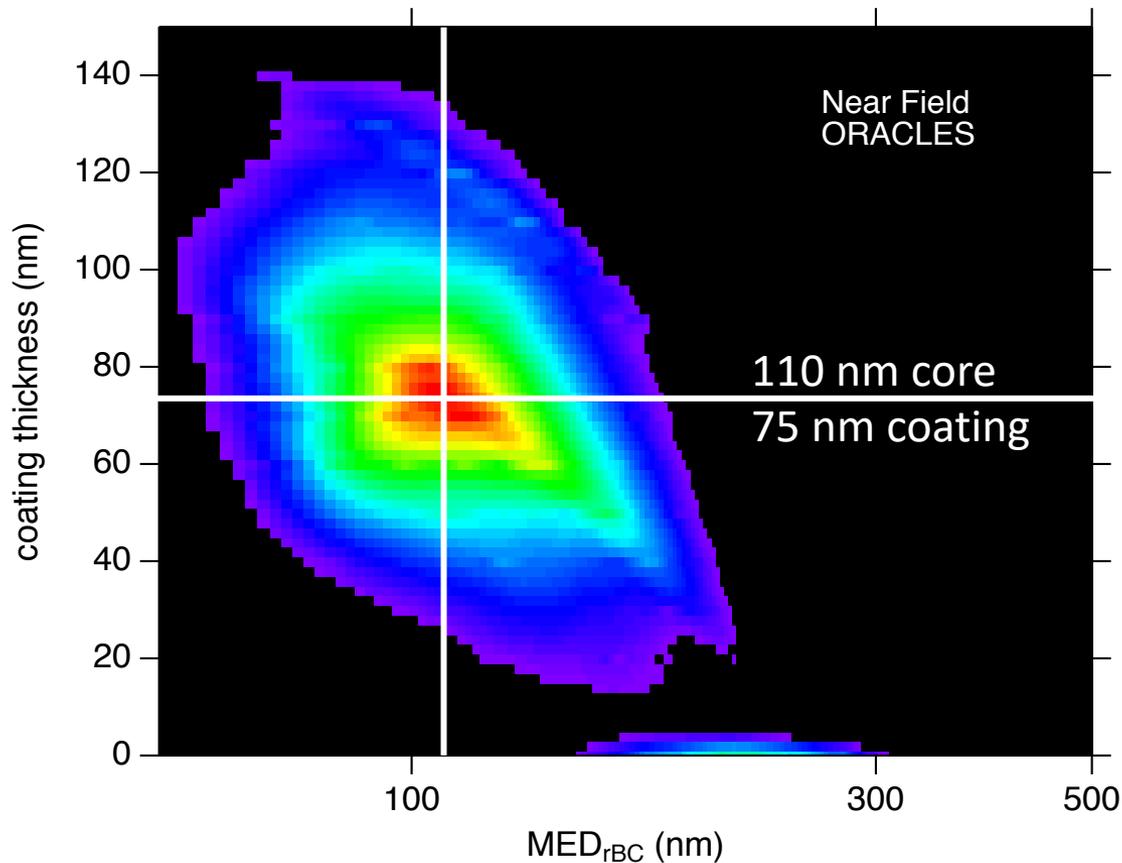

> 1 wk

What drives the observed changes in mixing state and the SSA behavior?

# rBC Particles are Thickly-Coated Nearest the African Coast

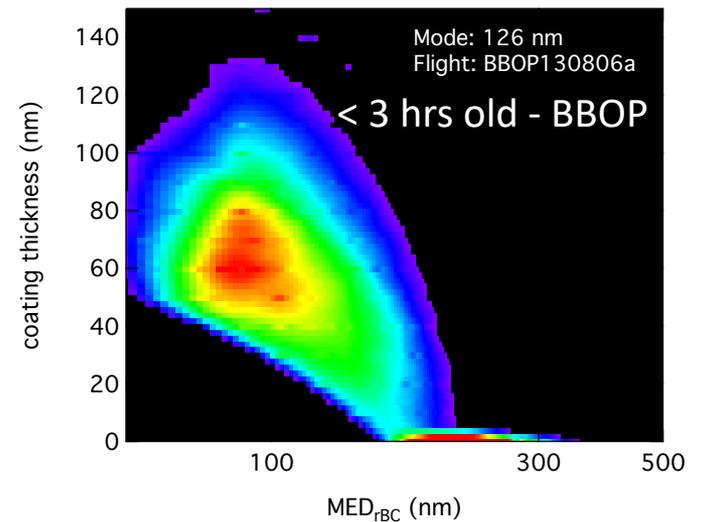

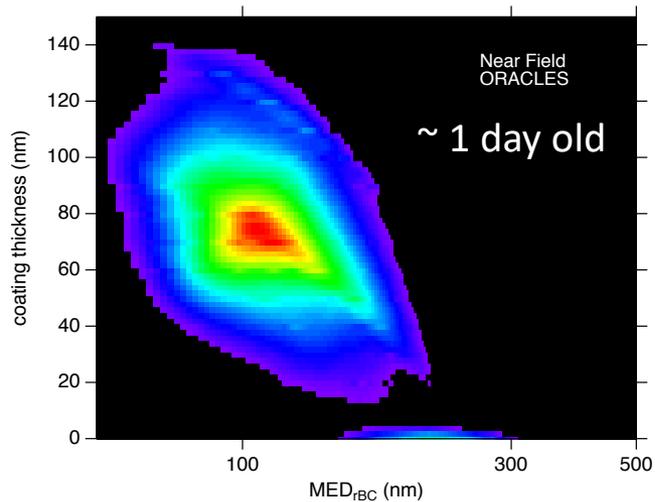

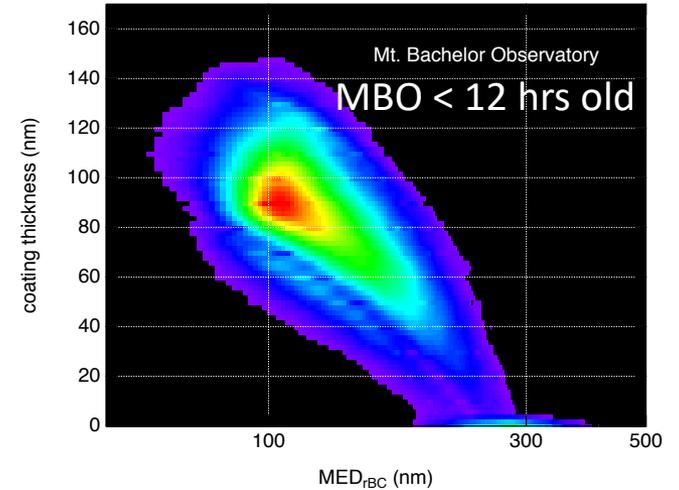

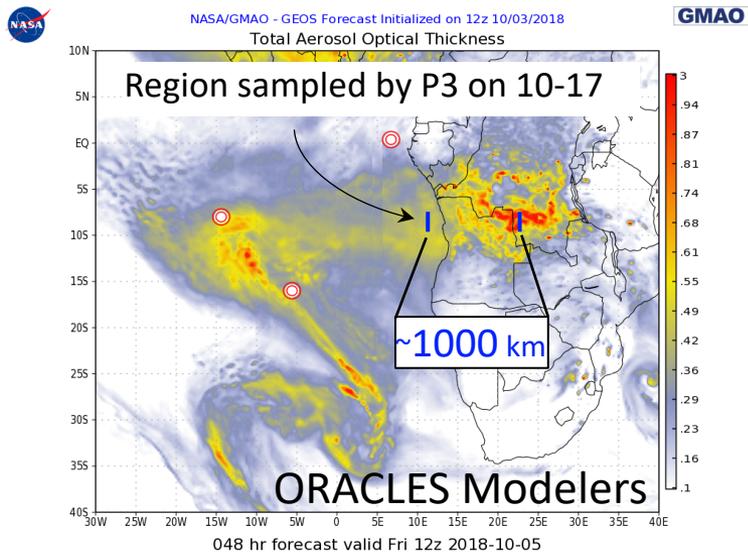

1) BC-coated particle is in core-shell configuration.

*Assumption supported by large coating thicknesses.*

$$\frac{\text{Coating mass}}{\text{rBC mass}} = 13$$

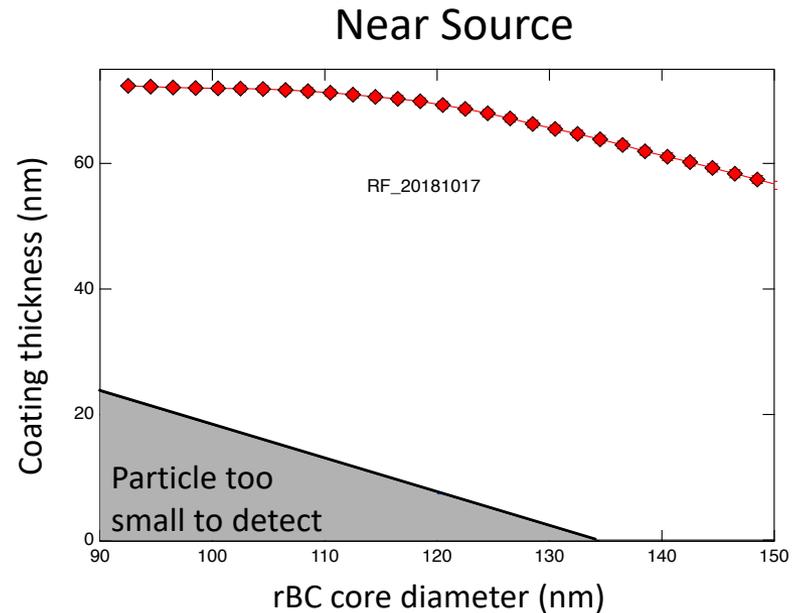

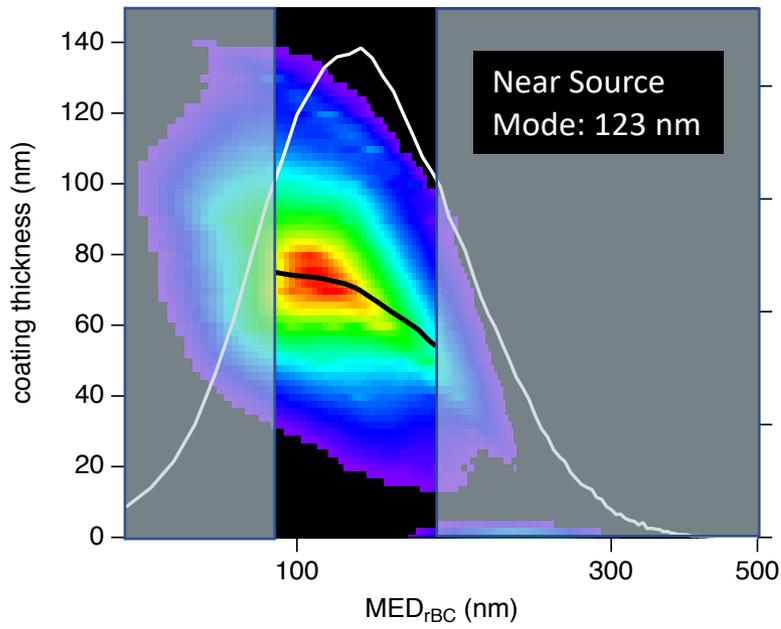

# Thickly-coated rBC particles in Near Source

Near source rBC mixing suggests negligible coating loss rBC particles from origin to P3 sampling point.

# Quantifying rBC Mixing State

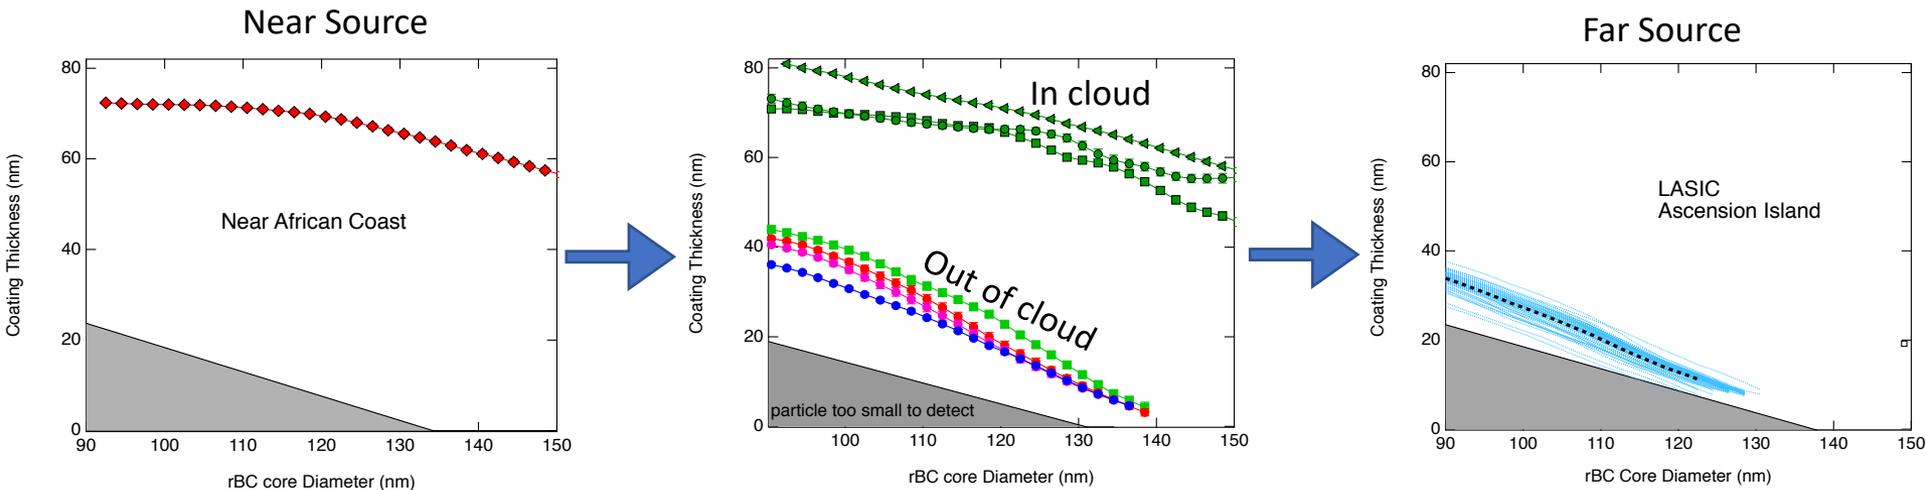

To better quantify the rBC-containing particle mixing state, only a subset of coating thicknesses are used so as to avoid detection limit issues discussed earlier.

For SP2 colleagues, the LEO methodology was employed in this mixing state analysis

# Variability in Derived rBC Coating Thicknesses

- Except for near source transect, all **ISO** inlet gives coating thicknesses < 40 nm for rBC dia=100 nm
- **CVI** inlet data spans the range from most thickly-coated particles to that observed in **ISO** inlet
- rBC particles analyzed from LASIC (Ascension island) exhibit the thinnest coatings

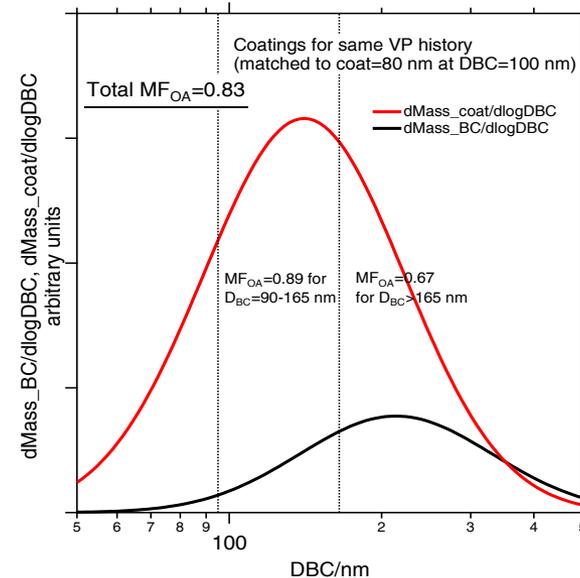

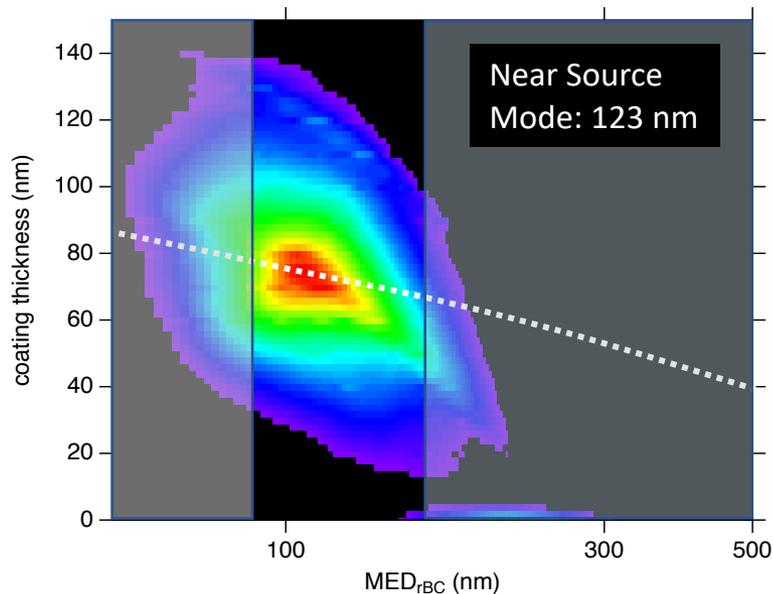

Cloud processing leaves behind only residual particles (i.e., smaller total diameter)

# Reconstructing Coated Core Mass Distribution

Coated particles experienced the same vapor-pressure history;  
thus, a given (coat,  $D_{BC}$ ) determines coating for any  $D_{BC}$ .

*Assumption supported by:*

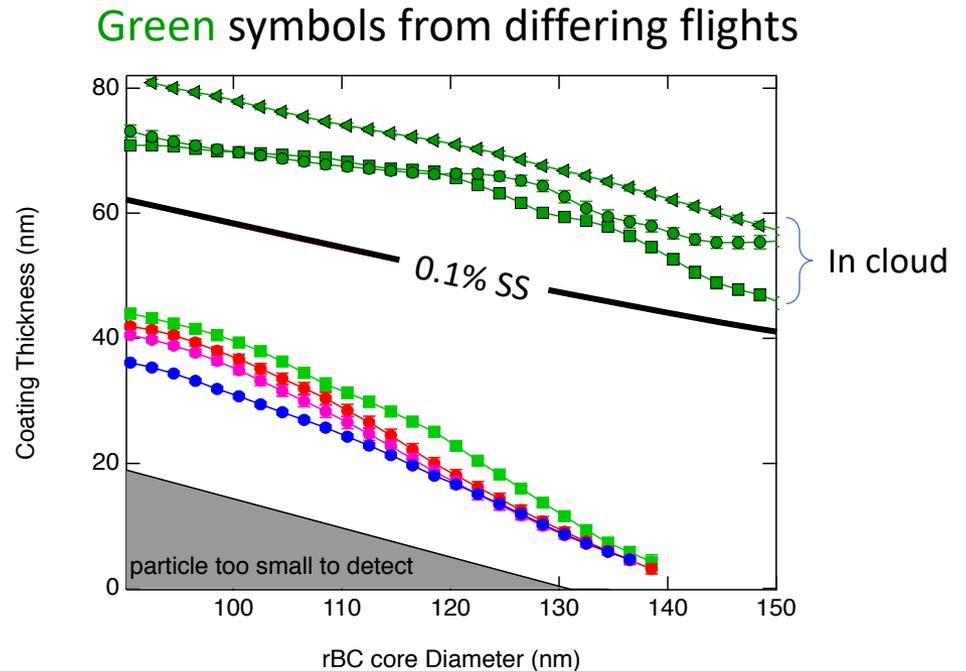

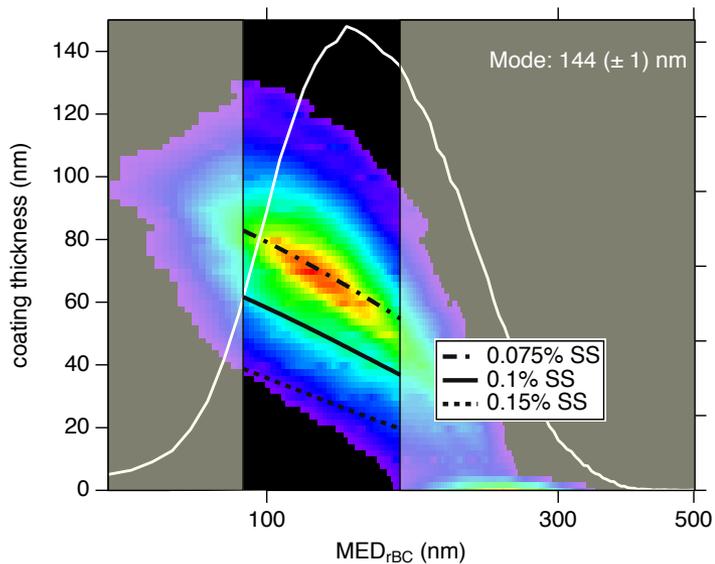

- 1) constant VP history line near max contours
- 2) steepness of contour lines
- 3) agreement of calculating mass fraction ( $MF_{OA}$ ) in region where SP2 determines both coat and  $D_{BC}$ : 0.93 by integration, 0.89 by constant VP line

# Activation of Coated rBC Cores

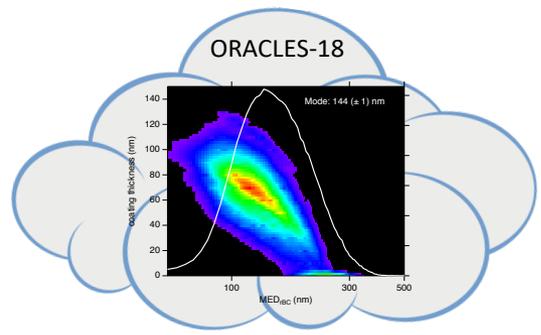

Activation: Kohler for core-shell (depends mainly on  $D_{\text{tot}}$ )

- $\kappa = 0.15$  (typical for organics)
- $s_{\text{crit}} = 0.1\%$  (insensitive, coupled to  $\kappa$ )

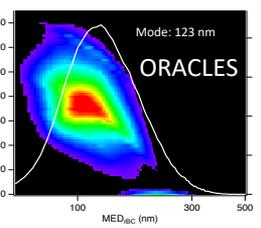

# rBC Particle Mixing States from LASIC & ORACLES

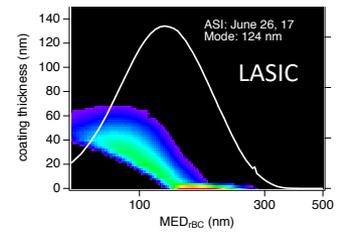

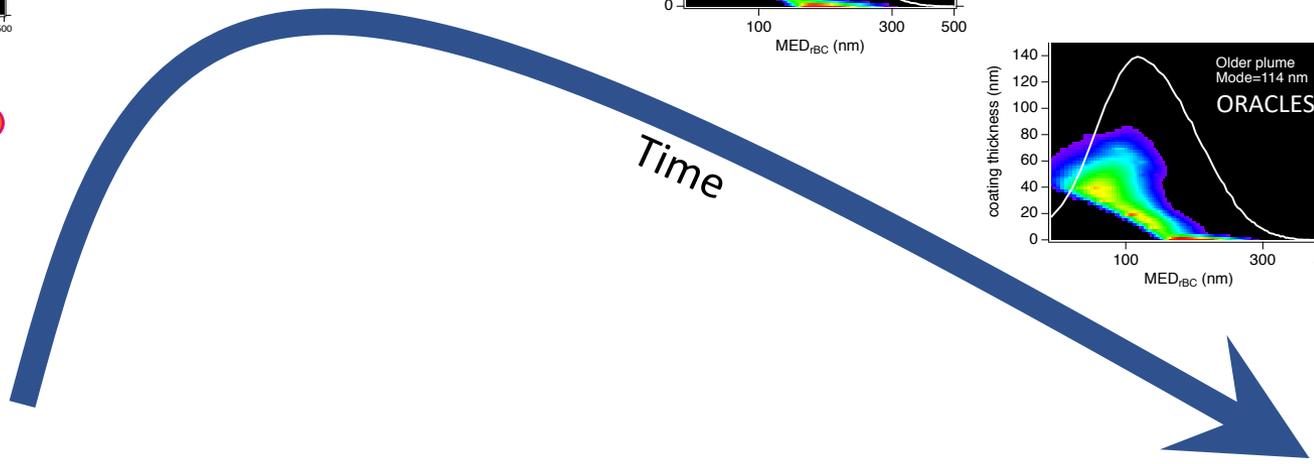

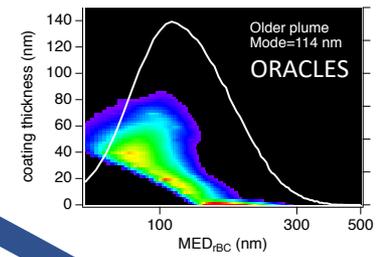

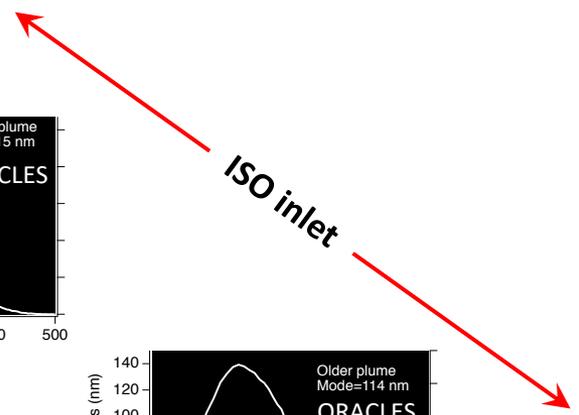

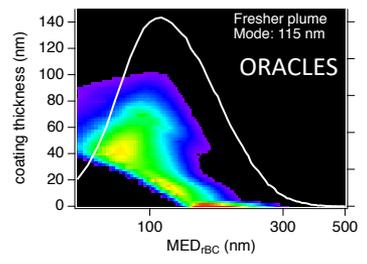

SSA ~ 0.9

ISO inlet

In cloud (CVI inlet)

> 1 wk

SSA ~ 0.8

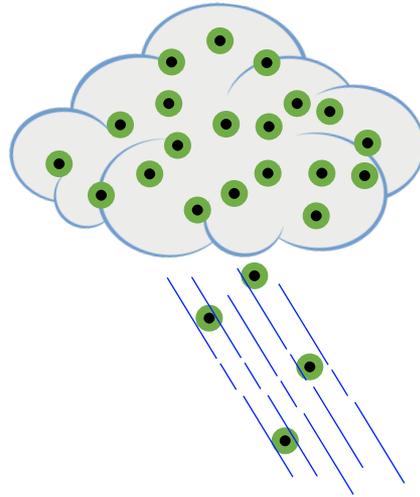

What drives the observed changes in mixing state and the SSA behavior?

Activation and/or cloud processing

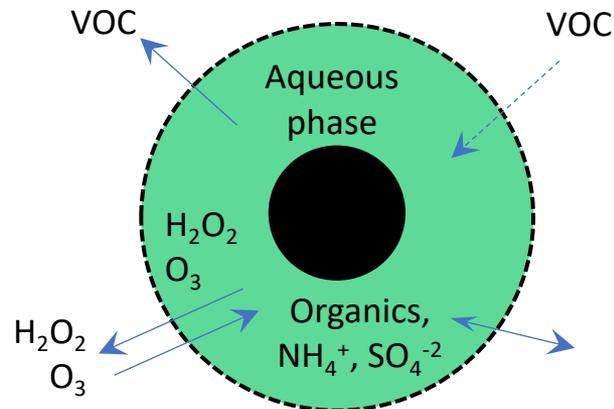

# How Might Activation Promote Coating Loss

---

- Wet deposition through precipitation

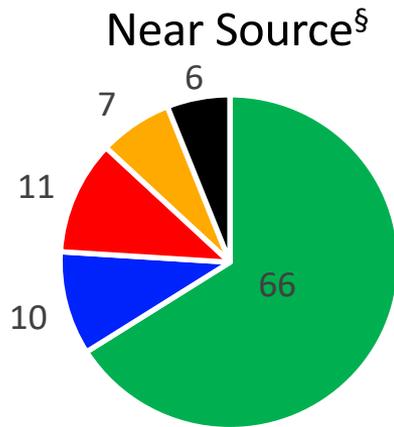

- Aqueous phase chemistry (molecular fragmentation → higher volatility species)

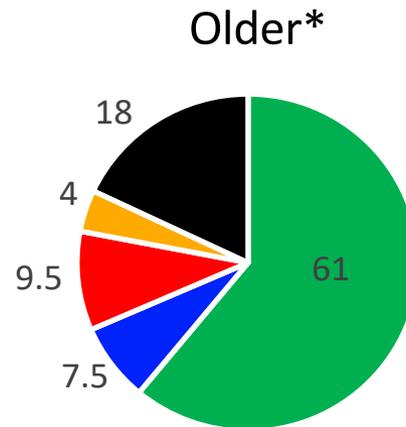

# Comparison of Model and Measurement of BB SSA

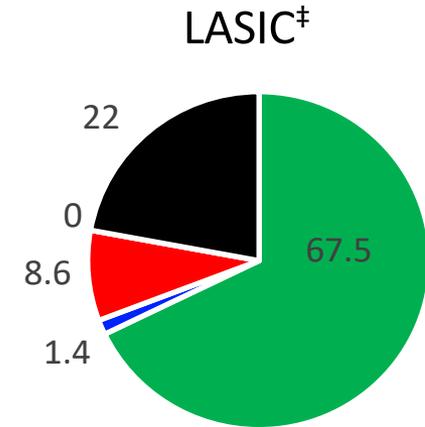

- rBC:  $RI=1.8 - 0.8*i$ ; BrC:  $RI=1.5-0.01*i$  (imaginary part restricted by initial SSA  $\sim 0.9$ )

$SSA_{calc}$ : 0.94  
 $SSA_{obs}$ :  $\sim 0.93$

$SSA_{calc}$ : 0.88  
 $SSA_{obs}$ :  $\sim 0.85$

$SSA_{calc}$ : 0.76  
 $SSA_{obs}$ :  $\sim 0.80$

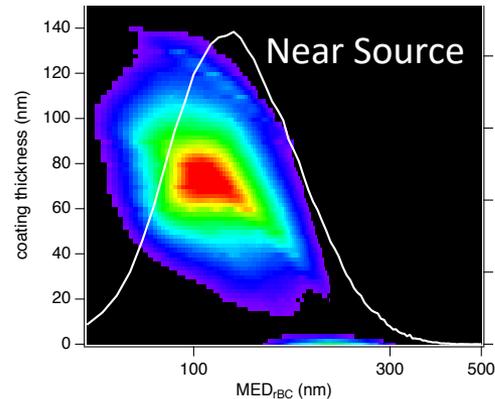

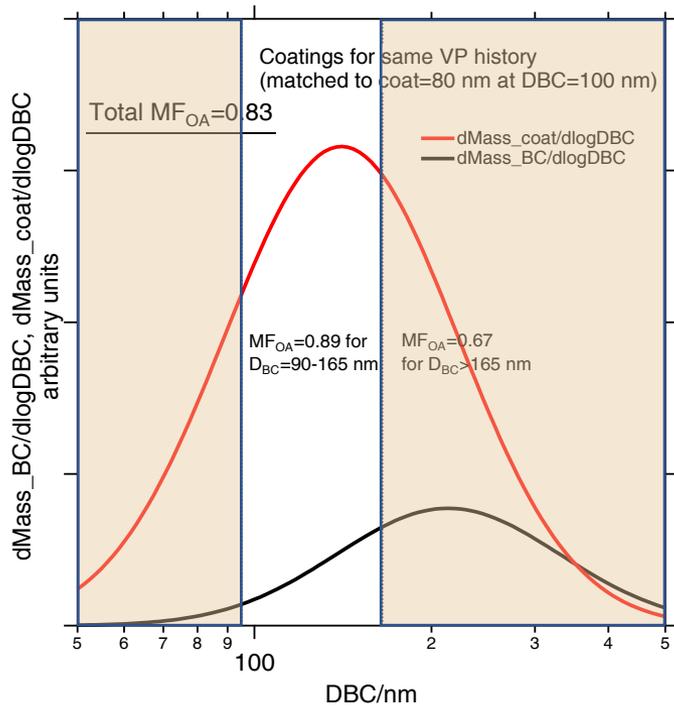

Greater proportion of rBC with time

# Model Prediction: Large Fraction of NR-Material is Coating

- Experimental measurement indicate the rBC cores are thickly coated
- Model presented here provides a way of estimating relative quantities (mass ratio)

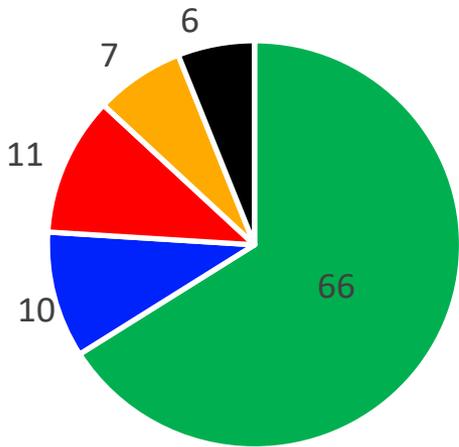

$$\frac{\text{Coating mass}}{\text{rBC mass}} = 13$$

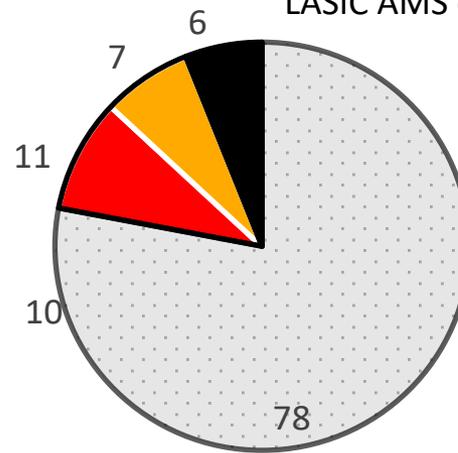

$$\frac{\text{Coating mass}}{\text{rBC mass}} = 2.8$$

# How Much OA is Bound with rBC?

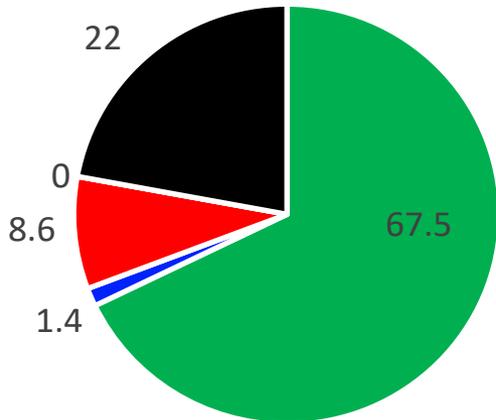

ORACLES AMS data courtesy of A. Dobracki  
 LASIC AMS data courtesy of A. Atkin et al.

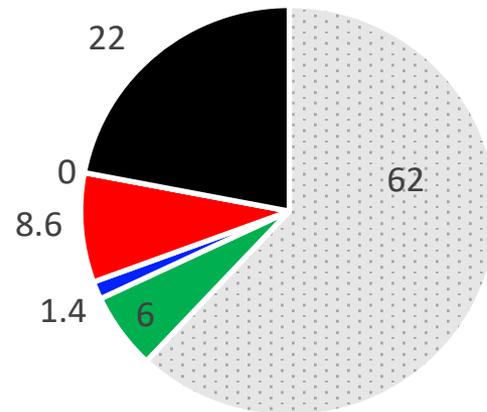

Near African Coast  
(Near source)

$$\frac{\text{Coating mass}}{\text{rBC mass}} = 13$$

Ascension Island

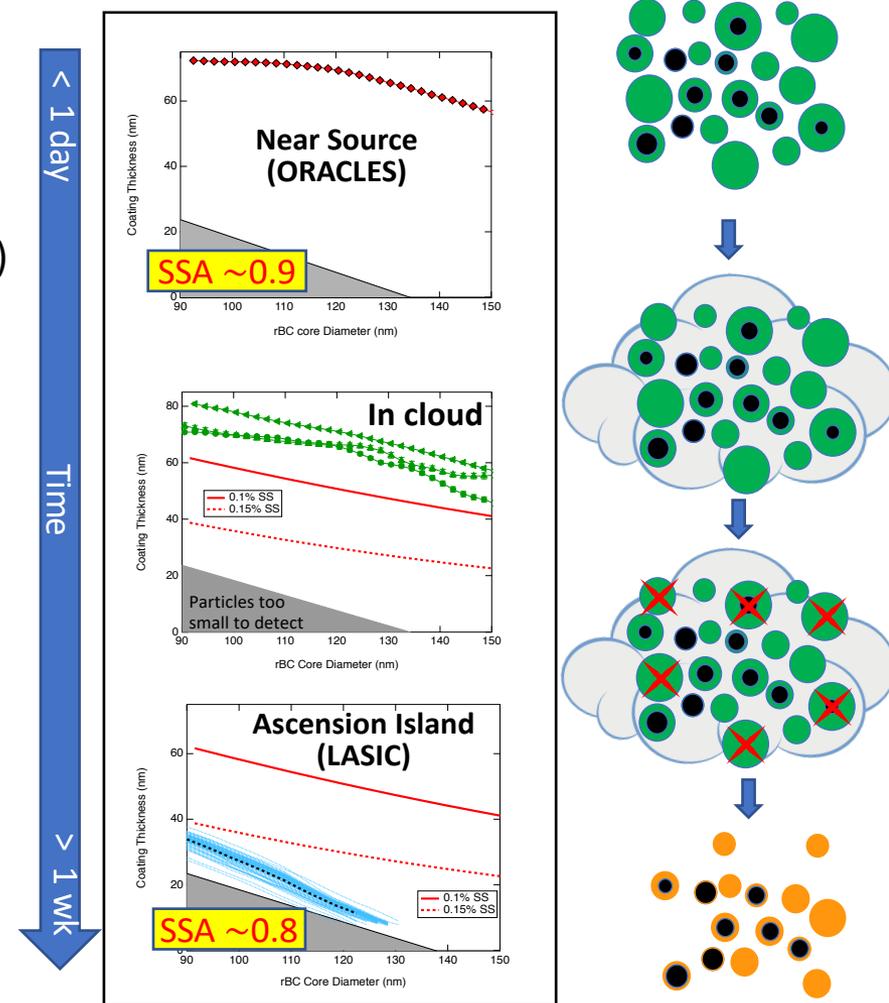

$$\frac{\text{Coating mass}}{\text{rBC mass}} = 2.8$$

A substantial fraction of non-refractory material is bound with rBC!

# Activation/Cloud Processing Drives BB Optical Property Evolution

## Take Home Messages

- BC from African biomass burns is thickly-coated in the near source and thinly-coated in the far field. (figs 1/3)
- SSA decreases from near source to far source. (figs 1/3)
- Thickly-coated BC particles are preferentially activated, enhancing their removal. (fig 2)
  - Reduction in light scattering
  - Decrease in SSA
  - Strong effect
- Brown Carbon (BrC) bleaching
  - Reduction in light absorption; little effect on scattering
  - Increase in SSA
  - Weak effect
- Much of the non-refractory material is bound with BC
- BrC plays secondary role to BC in determining SSA

Aerosol-cloud interactions in BB plumes drives BC to center stage

# Research Associate Position in Aerosol Microphysics

---

## **Research Associate for Aerosol Microphysics**

Research into the microphysical, optical, hygroscopic, and cloud-nucleating properties of aerosols, specifically light-absorbing aerosols, and how these properties affect radiation transmission through the atmosphere, including aerosol-cloud interactions.

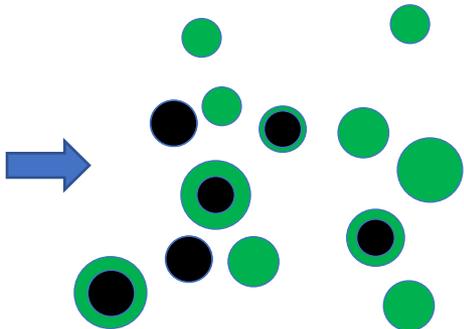

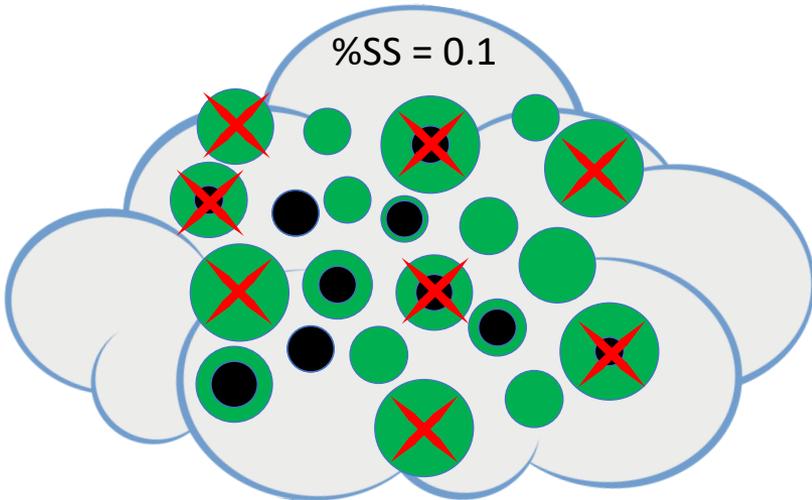

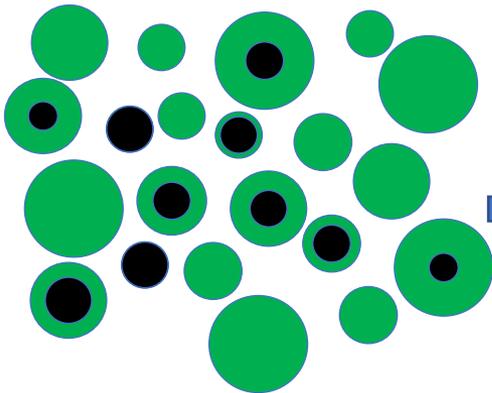

Our laboratory is outfitted with several state-of-the-art instruments that include the Single Particle Soot Photometer (SP2), Centrifugal Particle Mass Analyzer (CPMA), BNL-designed Photothermal Interferometer (PTI) for measurement of light absorption, and Cloud Condensation Nuclei (CCN) counter, along with core aerosol instrumentation (e.g., particle counters, scanning mobility particle sizer, particle generation).
